1 Homework 1

1.1 Exercise 2.1

Showing the definition of convexity for arbitrary k . $\theta_1 x_1 + \dots + \theta_k x_k \in C$.

$$\theta_1 x_1 + \dots + \theta_k x_k = \theta_1 x_1 + (1 - \theta_1)(\mu_2 x_2 + \mu_3 x_3 + \dots + \mu_k x_k) \quad (1)$$

Where each $\mu_n = \frac{\theta_n}{1 - \theta_1}$

$$\sum_i \mu_i = \frac{\sum_i \theta_i}{1 - \theta_1} = \frac{1 - \theta_1}{1 - \theta_1} = 1 \quad (2)$$

1.2 Exercise 2.2

The intersection between any two convex sets is convex. A line segment by definition is convex because it contains itself. Therefore, if there is any line segment L that intersects C , for C to be convex, the intersection must also be convex.

Similarly, for an affine set, the definition is that the set must contain the line through any distinct points in the set. Therefore if there is a line that line segment L that intersects an affine set A , its intersection is also affine.

1.3 Exercise 2.5

Distance between two parallel hyperplanes $\{x \in \mathbb{R}^n | a^T x = b_1\}, \{x \in \mathbb{R}^n | a^T x = b_2\}$:

$$a^T(x_1 + at) = b_2 \quad (3)$$

$$a^T x_1 + a^T at = b_2 \quad (4)$$

$$t = \frac{b_2 - a^T x_1}{a^T a} \quad (5)$$

$$t = \frac{b_2 - b_1}{a^T a} \quad (6)$$

$$\frac{|b_1 - b_2|}{\|a\|_2} \quad (7)$$

1.4 Exercise 2.7

The image below illustrates the intuition behind this in \mathbb{R}^2 . The set of all points that are closer to a than b $\{x | \|x - a\|_2 \leq \|x - b\|_2\}$, is a halfspace of the form

$$\{x | c^T x \leq d\} \quad (8)$$

where c is the normal vector that points from a to b , $c = \frac{a-b}{\|a-b\|_2}$ and $d = (\frac{a-b}{\|a-b\|_2})^T \frac{a+b}{2}$

1.5 Exercise 2.8

Finding which of the sets are polyhedra

1.5.1 a

$S = \{y_1 a_1 + y_2 a_2 \mid -1 \leq y_1 \leq 1, -1 \leq y_2 \leq 1\}$, $a_1, a_2 \in \mathbb{R}^n$ This set is a 2D parallelogram in any \mathbb{R}^n . The image shown is one that is generated with \mathbb{R}^3 coordinates $a_1 = (1, 2, 3)$ and $a_2 = (4, 5, 2)$. It can be defined as the intersection between four halfspaces with their normals pointing from the origin to and centered on $a_1, a_2, -a_1, -a_2$.

The normal vectors for the halfspaces are:

$$A = \begin{bmatrix} a_1 \\ \frac{\|a_1\|_2}{\|a_2\|_2} a_2 \\ -a_1 \\ \frac{\|a_1\|_2}{\|a_2\|_2} (-a_2) \end{bmatrix} \quad (9)$$

and the b vector is:

$$b = \begin{bmatrix} \|a_1\|_2 \\ \|a_2\|_2 \\ \|a_1\|_2 \\ \|a_2\|_2 \end{bmatrix} \quad (10)$$

Therefore, the set S can be expressed as $S = \{x | Ax \preceq b\}$

1.5.2 b

This is a polyhedra where:

$$A = I^n \quad (11)$$

$$b = 0 \quad (12)$$

$$C = \begin{bmatrix} 1 \\ a \\ a^2 \end{bmatrix} \quad (13)$$

$$d = \begin{bmatrix} 1 \\ b_1 \\ b_2 \end{bmatrix} \quad (14)$$

1.5.3 c

Not attempted

1.5.4 d

Not attempted

1.6 Exercise 2.11

Showing that the hyperbolic set $\{x \in \mathbb{R}_{++}^2 | x_1 x_2 \geq 1\}$ is convex. As a generalization, show that $\{x \in \mathbb{R}_+^2 | \prod_{i=1}^n x_i \geq 1\}$

1.7 Exercise 2.12

Finding which of the following sets are convex:

1.7.1 a. slab

A set of the form $\{x \in \mathbb{R}^n | \alpha \leq a^T x \leq \beta\}$, A slab is the intersection of two halfspaces \mathbb{C} and \mathbb{D} where $\mathbb{C} = \{x | a^T x \leq \beta\}$ and $\mathbb{D} = \{x | -a^T x \leq -\alpha\}$

1.7.2 b. rectangle

A set of the form $\{x \in \mathbb{R}^n | \alpha_i \leq x_i \leq \beta_i, i = 1, \dots, n\}$. This is also the intersection of halfspaces, but this time it is the intersection of four halfspaces (in \mathbb{R}^2). But this is a polyhedra.

1.7.3 c. wedge

A set of the form $\{x \in \mathbb{R}^n | a_1^T x \leq b_1, a_2^T x \leq b_2\}$. Intersection of two halfspaces

1.7.4 d. point-set distance

A set of the form $\{x | \|x - x_0\|_2 \leq \|x - y\|_2 \forall y \in S\}$ where $S \subseteq \mathbb{R}^n$. This can be viewed as the intersection of many euclidean balls. The intersection of convex spaces is convex so the here, the set can be turned into $\cap_{y \in S} \{x | \|x - x_0\|_2 \leq \|x - y\|_2\}$

1.7.5 e. set-set distance

A set of the form $\{x | \text{dist}(x, S) \leq \text{dist}(x, T)\}$ This set is not convex. Consider two crescent-moon shaped sets that lie next to each other so the tip of one moon is in the center of the other moon. The set that is closer to either of them is not convex because the crescent shape would stay in the set and is not convex.

1.7.6 f. affine set combo

A set of the form $\{x | x + S_2 \subseteq S_1\}$, where $S_1, S_2 \subseteq \mathbb{R}^n$ Yes, this is essentially the section of S_2 that can be translated to the convex S_1

1.7.7 g. fraction distance

Not attempted

1.8 Exercise 2.15

Finding which conditions sets are convex that are conditions on the probability simplex $\{p | \mathbf{1}^T p = 1, p \succeq 0\}$:

1.8.1 a. bounded expectation

This is a linear bound, so this set is convex.

1.8.2 b. prob a and b

Not attempted

2 Homework 2

2.1 Exercise 2.28

A matrix is positive semi-definite if we define two matrices symmetric A and Q , such that $Q(\mathbf{x}) = \mathbf{x}^T A \mathbf{x}$, Q and A are positive semidefinite if $Q(\mathbf{x}) \geq 0$ for all \mathbf{x} .

In other words, for a matrix A to be positive semidefinite, these two conditions must be satisfied:

- A is symmetric
- $x^T A x \geq 0$ for all x

The second condition can be broadened to multiple equivalent definitions:

- $x^T A x \geq 0$ for all x
- All eigenvalues are non-negative
- There exists a matrix B s.t. $B^T B = A$
- All principal minors are non-negative

2.1.1 $n=1$

For $n = 1$, the cone is defined by the inequality $x_1 \geq 0$

2.1.2 $n=2$

$$x_1 x_3 - x_2^2 \geq 0 \text{ and } x_1, x_3 \geq 0$$

2.1.3 $n=3$

All principal minors must be non-negative, so blocking off each row and column of the matrix.

Diagonals: $x_1, x_4, x_6 \geq 0$

Full matrix determinant: $x_1(x_4 x_6 - x_5^2) - x_2(x_2 x_6 - x_3 x_5) + x_3(x_2 x_5 - x_3 x_4) \geq 0$ 2x2 determinants: $x_4 x_6 - x_5^2 \geq 0$, $x_1 x_6 - x_3^2 \geq 0$, $x_1 x_4 - x_2^2 \geq 0$

2.2 Exercise 2.33

2.2.1 part a

A convex cone $K \subseteq \mathbb{R}^n$ is a proper cone if

- K is closed (contains its boundary)
- K is solid (nonempty interior)
- K is pointed (contains no line)

For this problem, we must show that the monotone non-negative cone defined as

$$K_{m+} = \{\mathbf{x} \in \mathbb{R}^n | x_1 \geq x_2 \geq \cdots \geq x_n \geq 0\} \quad (15)$$

is a proper cone.

Proving the first, where K_{m+} is closed and contains its boundary, we first find the boundary of K_{m+} . The boundaries are the two vectors in the direction of

$$\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix} \quad (16)$$

With magnitude x_1 . These boundaries clearly satisfy the \geq requirements of the set. If one of the conditions was a strict equality, then the convex cone would be open.

Proving the second, since all vectors are contained in between the boundaries, the set is solid.

Proving the third, because of the ≥ 0 requirement, the $\mathbf{x} \in \mathbb{R}^n$ of the set also have the $\mathbf{x} \succeq 0$ applicable. Therefore the cone is pointed.

Figure 1: Image of a monotone non-negative cone in \mathbb{R}^2

2.2.2 part b

Finding the dual cone K_{m+}^* . A dual cone is defined as

$$K^* = \{y | x^T y \geq 0 \text{ for all } x \in K\} \quad (17)$$

$$x^T y \quad (18)$$

$$= \sum_{i=1}^n x_i y_i \quad (19)$$

$$= (x_1 - x_2)y_1 + (x_2 - x_3)(y_1 + y_2) + \cdots + (x_{n-1} - x_n)(y_1 + \cdots + y_{n-1}) + x_n(y_1 + \cdots + y_n) \quad (20)$$

Since each term of y is getting multiplied by $x_i - x_{i+1}$, and $x_i \geq x_{i+1}$, each y term is getting multiplied by a non-negative x term, so if we want $x^T y \geq 0$ for all x , then we will need in the worst case scenario, for each one of the y terms to be positive.

$$y_1 \geq 0, y_1 + y_2 \geq 0, y_1 + y_2 + y_3 \geq 0, \dots, \sum_{i=1}^n y_i \geq 0 \quad (21)$$

These conditions are all satisfied when $y_n \geq y_{n-1} \geq \dots \geq y_2 \geq y_1 \geq 0$. Therefore, the dual cone is

$$K^* = \{y \in \mathbb{R}^n | y_n \geq y_{n-1} \geq \dots \geq y_2 \geq y_1 \geq 0\} \quad (22)$$

2.3 Exercise 3.2

The first function is potentially quasiconvex because the sublevel sets shown are convex. The second function does not seem to have convex sublevel sets. So it is not quasiconvex or quasiconcave.

2.4 Exercise 3.5

Showing that the running average of a convex function is also convex. Since f is differentiable, we can attempt to differentiate F twice and evaluate it on the domain of F

$$F(x) = \frac{1}{x} \int_0^x f(t) dt \quad (23)$$

$$F'(x) = -\frac{1}{x^2} \int_0^x f(t) dt + \frac{1}{x} \frac{d}{dx} \int_0^x f(t) dt \quad (24)$$

$$= -\frac{1}{x^2} \int_0^x f(t) dt + \frac{1}{x} (f(x) + \int_0^x \frac{d}{dx} f(t) dt) \quad (25)$$

$$F'(x) = -\frac{1}{x^2} \int_0^x f(t) dt + \frac{f(x)}{x} \quad (26)$$

$$F''(x) = \frac{2}{x^3} \int_0^x f(t) dt - \frac{1}{x^2} \frac{d}{dx} \int_0^x f(t) dt + \frac{f'(x)x - f(x)}{x^2} \quad (27)$$

$$F''(x) = \frac{2}{x^3} \int_0^x f(t) dt - \frac{f(x)}{x^2} + \frac{f'(x)x - f(x)}{x^2} \quad (28)$$

$$F''(x) = \frac{2}{x^3} \int_0^x f(t) dt - \frac{2f(x)}{x^2} + \frac{f'(x)x}{x^2} \quad (29)$$

$$F''(x) = \frac{2}{x^3} \left(\int_0^x f(t) dt - f(x)x + \frac{f'(x)x^2}{2} \right) \quad (30)$$

$$= \frac{2}{x^3} \left(\int_0^x f(t) - f(x) - f'(x)(t-x) dt \right) \quad (31)$$

The term $f(t) - f(x) - f'(x)(t-x)$ is always positive because of the definition below for any convex function f

$$f(t) \geq f(x) + f'(x)(t-x) \quad (32)$$

Therefore, since the domain of F is confined to all positive numbers, the hessian of F is always greater than zero.

2.5 Exercise 3.6

- The epigraph of a function is a halfspace if the function is affine. Since the function is linear and infinite, its epigraph is a halfspace.
- If a function is linear then its epigraph is a convex cone.
- If a function is piecewise affine, then its epigraph is a polyhedron.

2.6 Exercise 3.15

2.6.1 part a

Showing that for $x > 0$, $u_0(x) = \lim_{\alpha \rightarrow 0} u_\alpha(x)$

$$u_\alpha(x) = \frac{x^\alpha - 1}{\alpha} \quad (33)$$

L'hospital :)

$$\lim_{\alpha \rightarrow 0} \frac{x^\alpha - 1}{\alpha} = \lim_{\alpha \rightarrow 0} x^\alpha \log x \quad (34)$$

This goes to $\log x$ as $\alpha \rightarrow 0$

2.6.2 Part b

Firstly, u_α is monotonically increasing because the first derivative is

$$u'_\alpha = x^{\alpha-1} \quad (35)$$

Which is always positive. The function is concave since the hessian is

$$u''_\alpha = (\alpha - 1)x^{\alpha-2} \quad (36)$$

Since $0 < \alpha \leq 1$, the function is affine for $\alpha = 1$ and concave for all other values of α . The equation $u_\alpha(1) = 0$ is also satisfied since $1^\alpha = 1 \forall \alpha$

2.7 Exercise 3.16

Finding whether the functions are convex, concave, quasiconcave, or quasiconvex.

2.7.1 Part b

$$f(x_1, x_2) = x_1 x_2 \quad (37)$$

$$\nabla^2 f = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (38)$$

In reducing to row echelon form, rows 1 and 2 would need to exchange and therefore the matrix is not positive semidefinite and not convex. It is not concave since the negative of the matrix is not positive semidefinite. It is quasiconcave but I didn't really know that.

2.7.2 Part c

$$f(x_1, x_2) = \frac{1}{x_1 x_2} \quad (39)$$

$$\nabla^2 f = \begin{bmatrix} \frac{2}{x_1^3 x_2} & \frac{1}{x_1^2 x_2^2} \\ \frac{1}{x_1^2 x_2^2} & \frac{2}{x_1 x_2^3} \end{bmatrix} \quad (40)$$

This function is convex if $\frac{2}{x_1^3 x_2} \geq 0$ and $\frac{3}{x_1^4 x_2^4} \geq 0$. Since $x_1, x_2 \in \mathbb{R}_{++}^2$, the function is convex.

2.7.3 Part d

$$f(x_1, x_2) = \frac{x_1}{x_2} \quad (41)$$

$$\nabla^2 f = \begin{bmatrix} 0 & \frac{-1}{x_2^2} \\ \frac{-1}{x_2^2} & \frac{2x_1}{x_2^3} \end{bmatrix} \quad (42)$$

This function is not convex or concave. I still don't really get quasiconvex or quasiconcave tbh.

2.7.4 Part e

$$f(x_1, x_2) = \frac{x_1^2}{x_2} \quad (43)$$

I know this is convex because I watched the lecture but here the hessian

$$\nabla^2 f = \begin{bmatrix} \frac{2}{x_2} & \frac{-2x_1}{x_2^2} \\ \frac{-2x_1}{x_2^2} & \frac{2x_1^2}{x_2^3} \end{bmatrix} \quad (44)$$

This function is convex when its hessian is positive semidefinite, which is satisfied when $\frac{2}{x_2} \geq 0$, $\frac{2x_1^2}{x_2^3} \geq 0$ and $\frac{4x_1^2}{x_2^4} - \frac{4x_1^2}{x_2^4} \geq 0$. These are always true and therefore f is convex.

2.8 Exercise 3.18

Not attempted

2.9 Exercise 3.24

Finding if the below probability simplexes are convex, quasiconvex, concave, quasiconcave

2.9.1 quartile

$$\text{quartile}(x) = \inf\{\beta \mid \mathbf{prob}(x \leq \beta) \geq 0.25\} \quad (45)$$

This function is quasiconvex and quasiconcave. It is not convex since it is not continuous

2.10 Exercise 3.36

Deriving conjugates of the function

2.10.1 Max function

$$f^*(y) = \sup\{y^T x - f(x)\} \quad (46)$$

$$f^*(y) = \sup\{y^T x - \max\{x_i\}\} \quad (47)$$

$$\frac{d}{dx} y^T x - \max\{x_i\} = y - \quad (48)$$

3 Homework 3

3.1 Exercise 3.42

For this problem we have to show that the below function is quasiconcave

$$W(x) = \sup\{T \mid |x_1 f_1(t) + \cdots + x_n f_n(t) - f_0(t)| \leq \epsilon \text{ for } 0 \leq t \leq T\} \quad (49)$$

To prove this, we can find if for each ϵ , the function is concave. The definition of quasiconcavity is that all its superlevel sets are concave. In order to evaluate the superlevel sets, we can flip the infimum and supremum

$$W(x) = \inf\{T \mid |x_1 f_1(t) + \cdots + x_n f_n(t) - f_0(t)| \geq \epsilon \text{ for } 0 \leq t \leq T\} \quad (50)$$

This form of the equation now flips the equal sign so we can evaluate the superlevel sets with the threshold being ϵ . The point-wise infimum of a set of concave functions is a concave function. So, as long as the function inside is a concave function, then this holds. The function there is a linear combination of x and therefore it is convex, and therefore quasiconcave.

3.2 Exercise 3.54

Verifying log concavity of the the function

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt \quad (51)$$

3.2.1 Part a

Verifying that $f''(x)f(x) \leq f'(x)^2, x \geq 0$

$$f'(x) = \frac{1}{\sqrt{2\pi}} \frac{d}{dx} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt \quad (52)$$

$$= \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} \quad (53)$$

$$f''(x) = \frac{1}{\sqrt{2\pi}} \frac{d}{dx} e^{-\frac{x^2}{2}} \quad (54)$$

$$= -\frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} x \quad (55)$$

$$f''(x)f(x) \leq f'(x)^2 \quad (56)$$

$$-\frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} x \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt \leq \left(\frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}} \right)^2 \quad (57)$$

$$-e^{-\frac{x^2}{2}} x \int_{-\infty}^x e^{-\frac{t^2}{2}} dt \leq (e^{-\frac{x^2}{2}})^2 \quad (58)$$

If $x = 0$, the inequality $0 \leq 1$ holds. If $x > 0$, the left hand side of the inequality will always be negative and the right hand side will be greater than 1. Therefore the statement $f''(x)f(x) \leq f'(x)^2, x \geq 0$ holds.

3.2.2 Part b

Verifying that for any t and x , we have $\frac{t^2}{2} \geq -\frac{x^2}{2} + xt$ I am not sure the most rigorous way to do this, so I will evaluate the signs of each side on every combination of zero, positive, and negative.

- $x = 0, t = 0 \rightarrow 0 \geq 0 \Rightarrow$ evidently true since zero equals zero
- $x > 0$ or $x < 0, t = 0 \rightarrow 0 \geq -\frac{x^2}{2} \Rightarrow$ evidently true since a negative number is lower than zero
- $x = 0, t > 0$ or $t < 0 \rightarrow \frac{t^2}{2} \geq 0 \Rightarrow$ evidently true since a positive number is greater than zero
- $x < 0, t > 0 \rightarrow \frac{t^2}{2} \geq -\frac{x^2}{2} - |x|t$ evidently true since a positive number is greater than a negative number
- $x < 0, t < 0 \rightarrow t^2 + x^2 \geq 2|x||t|$ this is the arithmetic-geometric mean inequality

3.2.3 Part c

Part b can be flipped and applying log to both sides we see that $e^{-\frac{t^2}{2}} \leq e^{\frac{x^2}{2} - xt}$

$$e^{-\frac{t^2}{2}} \leq e^{\frac{x^2}{2} - xt} \quad (59)$$

$$\int_{-\infty}^x e^{-\frac{t^2}{2}} dt \leq \int_{-\infty}^x e^{\frac{x^2}{2} - xt} dt \quad (60)$$

$$\int_{-\infty}^x e^{-\frac{t^2}{2}} dt \leq e^{\frac{x^2}{2}} \int_{-\infty}^x e^{-xt} dt \quad (61)$$

3.2.4 Part d

$$\int_{-\infty}^x e^{-\frac{t^2}{2}} dt \leq -e^{-\frac{x^2}{2}} x \quad (62)$$

3.3 Exercise 3.57

Showing that the function $f(X) = X^{-1}$ is matrix convex on \mathbb{S}_{++}^n . If the matrix X is positive definite, then its inverse is also positive definite and therefore matrix convex.

3.4 Exercise 4.4

3.4.1 Part a

Proving that for any $x \in \mathbb{R}^n$ we have $\bar{x} \in \mathbb{F}$ where \mathbb{F} is

$$\mathbb{F} = \{x | Q_i x = x, i = 1, \dots, k\} \quad (63)$$

Since $\bar{x} = \frac{1}{k} \sum_{i=1}^k Q_i x$ and the group \mathbb{G} is closed under products and inverse, any multiplication of the matrices Q_i and Q_j will result in some other Q_s . Therefore, $\frac{1}{k} \sum_{s=1}^k Q_s x = \frac{1}{k} \sum_{i=1}^k Q_i x$

3.4.2 Part b

Showing that if $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is convex and \mathbb{G} -invariant, then $f(\bar{x}) \leq f(x)$.

$$f(\bar{x}) = f\left(\frac{1}{k} \sum_{i=1}^k Q_i x\right) \quad (64)$$

$$\text{Since } f \text{ is convex} \quad (65)$$

$$f\left(\frac{1}{k} \sum_{i=1}^k Q_i x\right) \leq \frac{1}{k} \sum_{i=1}^k f(Q_i x) \quad (66)$$

$$\text{Since } f \text{ is } \mathbb{G}\text{-invariant} \quad (67)$$

$$f\left(\frac{1}{k} \sum_{i=1}^k Q_i x\right) \leq \frac{1}{k} \sum_{i=1}^k f(x) \quad (68)$$

$$f(\bar{x}) \leq f(x) \quad (69)$$

3.4.3 Part c

If every function in the optimization problem below is \mathbb{G} -invariant, then there exists an equivalent optimization problem

$$\begin{aligned} & \text{minimize } f_0(Q_i x) \\ & \text{subject to } f_i(Q_i x) \leq 0, i = 1, \dots, m \\ & \quad Q_i x - x = 0 \end{aligned} \quad (70)$$

3.4.4 Part d

Not attempted

3.5 Exercise 4.8

3.5.1 Part a

$$c^T x + \lambda^T (Ax - b) \quad (71)$$

$$\frac{d}{dx} = c + A^T \lambda = 0 \quad (72)$$

$$x^T c + x^T A^T \lambda - \lambda^T b \quad (73)$$

$$x^T (c + A^T \lambda) - \lambda^T b \quad (74)$$

$$p^* = \lambda^T b \iff c = A^T \lambda \quad (75)$$

Otherwise the problem is either infeasible so the the value would be $-\infty$, or the problem is unbounded and therefore ∞

3.5.2 Part b

$$c^T x + \lambda(a^T x - b) \quad (76)$$

$$c + a\lambda = 0 \quad (77)$$

$$c = a\lambda \quad (78)$$

$$p^* = b\lambda \iff c = a\lambda \quad (79)$$

3.5.3 Part c

If c is positive, then the minimization goes to the lower bound l , otherwise, it goes to the upperbound u if c is negative. All feasible values are optimal if $c = 0$

3.5.4 Part d

$$\begin{aligned} & \text{minimize } c^T x \\ & \text{subject to } \mathbf{1}^T x = 1 \\ & \quad x \succeq 0 \end{aligned} \quad (80)$$

In this case, regardless of the sign of c , the optimal value will be the smallest entry c_{min} . This is because if all entries are positive, then the smallest entry will be maxed out by the corresponding $x_i = 1$ and the rest $x_j \neq i = 0$. And if the entries are negative, then the value is still maxed out at $x_i = 1$.

3.5.5 Part e

Not attempted

3.6 Exercise 4.17

$$\begin{aligned} & \text{maximize } \sum_{j=1}^n r_j(x_j) \\ & \text{subject to } Ax \preceq c^{max} \\ & \quad x \succeq 0 \end{aligned} \quad (81)$$

Transforming

$$\begin{aligned} & \text{maximize } p^T x_{under} + p_{disc}^T x_{over} \\ & \text{subject to } Ax \preceq c^{max} \\ & \quad x_{under} - q = x_{over} \\ & \quad x_{under}, x_{over} \succeq 0 \end{aligned} \quad (82)$$

with variables x_{under} and x_{over}

4 Homework 4

4.1 Exercise 4.11

The task is to formulate different norms as LPs

4.1.1 Part a

Minimizing $\|Ax - b\|_\infty$. This norm is the same as the maximum entry of $Ax - b$

$$\min \|Ax - b\|_\infty = \min \max\{A_i x - b_i, i = 1, \dots, n\} \quad (83)$$

$$\begin{aligned} & \min z \\ & \text{subject to } z \geq A_i x - b_i, i = 1, \dots, n \end{aligned} \quad (84)$$

4.1.2 Part b

Minimizing $\|Ax - b\|_1$. The l_1 norm is equal to

$$\sum_i |A_i x - b_i| \quad (85)$$

where A_i is the i -th row of the matrix A . We can turn this into

$$\begin{aligned} & \text{minimize } \sum_i |z_i| \\ & \text{subject to } z_i = A_i x - b_i; i = 1, \dots, m \end{aligned} \quad (86)$$

Removing the absolute value

$$\begin{aligned} & \text{minimize } \sum_i z_i \\ & \text{subject to } A_i x - b_i \leq z_i; i = 1, \dots, m \\ & \quad b_i - A_i x \leq z_i; i = 1, \dots, m \end{aligned} \quad (87)$$

Vector notation

$$\begin{aligned} & \text{minimize } \mathbf{1}^T z \\ & \text{subject to } Ax - b \preceq z \\ & \quad b - Ax \preceq z \end{aligned} \quad (88)$$

4.1.3 Part c

Minimizing $\|Ax - b\|_1$ subject to $\|x\|_\infty \leq 1$

$$\begin{aligned} & \text{minimize } \mathbf{1}^T z \\ & \text{subject to } Ax - b \preceq z \\ & \quad b - Ax \preceq z \\ & \quad \|x\|_\infty \leq 1 \end{aligned} \quad (89)$$

Expanding the l_∞ norm

$$\begin{aligned}
& \text{minimize } \mathbf{1}^T z \\
& \text{subject to } Ax - b \preceq z \\
& \quad b - Ax \preceq z \\
& \quad x \preceq \mathbf{1} \\
& \quad -x \preceq \mathbf{1}
\end{aligned} \tag{90}$$

4.1.4 Part d

Minimizing $\|x\|_1$ subject to $\|Ax - b\|_\infty \leq 1$

$$\begin{aligned}
& \text{minimize } \mathbf{1}^T z \\
& \text{subject to } x \preceq z \\
& \quad -x \preceq z \\
& \quad Ax - b \preceq \mathbf{1} \\
& \quad b - Ax \preceq \mathbf{1}
\end{aligned} \tag{91}$$

4.1.5 Part e

Minimizing $\|Ax - b\|_1 + \|x\|_\infty$

$$\begin{aligned}
& \text{minimize } \mathbf{1}^T z + s \\
& \text{subject to } x \preceq s \\
& \quad -x \preceq s \\
& \quad Ax - b \preceq z \\
& \quad b - Ax \preceq z
\end{aligned} \tag{92}$$

4.2 Exercise 4.16

The minimum fuel optimal control problem as an LP. First, starting with what was given in the problem with minimal changes:

$$\begin{aligned}
& \text{minimize } \sum_{t=0}^{N-1} f(u(t)) \\
& \text{subject to } x(t+1) = Ax(t) + bu(t) \\
& \quad x(N) = x_{des} \\
& \quad x(0) = 0
\end{aligned} \tag{93}$$

not sure how to do this one

4.3 Exercise 4.29

4.4 Exercise 4.30

4.5 Exercise 5.1

Looking at the optimization problem

$$\begin{aligned}
& \text{minimize } x^2 + 1 \\
& \text{subject to } (x-2)(x-4) \leq 0
\end{aligned} \tag{94}$$

4.5.1 Part a

The feasible set is the interval from $[2, 4]$. The optimal value is 5 and the optimal solution is $x = 2$

4.5.2 Part b

Solving for the lagrangian

$$\begin{aligned}
 L(\lambda, x) &= x^2 + 1 + \lambda(x - 2)(x - 4) \\
 g(\lambda) &= \inf_x L(\lambda, x) \\
 \frac{d}{dx} x^2 + 1 + \lambda(x - 2)(x - 4) &= 2x + \lambda(2x - 6) \\
 2x + \lambda 2x &= 6\lambda \\
 x &= \frac{3\lambda}{1 + \lambda} \\
 g(\lambda) &= \left(\frac{3\lambda}{1 + \lambda}\right)^2 + 1 + \lambda\left(\left(\frac{3\lambda}{1 + \lambda}\right) - 2\right)\left(\frac{3\lambda}{1 + \lambda} - 4\right)
 \end{aligned} \tag{95}$$
